TECH TIP: XANTHOMONAS PREVENTION AND CONTROL

Infected plants cannot be treated curatively for bacterial leaf spot (BLS). This means exclusion is the best first line of defense. Frequent scouting and rapid response to early symptoms is critical to contain an outbreak if Xanthomonas does enter your operation. Here are some general best-practices and management suggestions to follow to prevent and contain an outbreak:

- For seed-propagated crops, always buy tested seed, plugs or finished material from suppliers who grew them from tested seed.
- For vegetatively propagated crops (like begonias), always purchase liners from trusted suppliers. Scout incoming material rigorously and quarantine liners from different suppliers and/or breeding companies for observation before planting. Shipping stress can be the catalyst for infection and symptom expression, so enacting a brief holding period before planting and finished production can help catch a latent infestation.
- Splashing water is the primary mode of transmission between plants, so avoid overhead watering of *Xantho*-prone crops.
- Drip irrigation for larger containers and hanging baskets is a great strategy.
- If all watering is done by hand with a hose and breaker, water as close to the base of plants as possible.
- Good sanitation is critical to reduce spread. Throw away infected plants and leaves or plant
 debris—do not compost them. Apply a sanitizing agent to the growing area ASAP after disposal;
 products with quaternary ammonia as the active ingredient are highly effective.
- After watering, dry the crop canopy down as quickly as possible. Reduce relative humidity in the
 greenhouse by venting more frequently, increase air flow with HAF fans, and space plants as
 wide as possible to increase air flow and reduce canopy drying time.
- Copper-based products, mancozeb, and some biological/biorational products can help to prevent the spread of *Xanthomonas*. However, bactericides must be applied before infection and disease occurs. Reactive applications to infected plants may slow disease progression but will not work curatively. Also, be aware of label restrictions when applying bactericidal products to "edible" crops.
