# GrowerFacts

# Felicia Blue

(Felicia amelloides)

# **Propagation**

# STAGE 1 - Harvesting of cuttings to sticking

- · Harvest uniform diameter cuttings to ensure uniform rooting.
- Make multiple passes over the stock to collect uniform diameter cuttings.
- Harvest cuttings at the correct stage of maturitybe certain stem cuttings are not woody.
- Harvest cuttings in the early morning or late afternoon when ambient temperatures are below 90°F (32°C).
- Place cuttings in carriers either base up or base down.
- Avoid crushing the cuttings when harvesting to decrease botrytis problems.
- Cover the carrier with a damp towel to prevent desiccation of the cuttings.
- Store the cuttings for at least 2 hours at 48°F (9°C) to reduce cutting temperature.

  Maintain 75-90% RH in the cooler to prevent
- desiccation of the cuttings.
- If planting is going to be delayed, store the cuttings at 50-60°F (10-16°C) for 24 hours maximum.

#### STAGE 2 - Callus formation (5-7 days)

- · Callus formation occurs in 4 steps:
  - 1. Swelling of the tissue without any color change.
  - Swollen area begins to turn white
  - White areas begin to crack open (epidermis ruptures)
  - Rough callus areas begin differentiating root initials.
- Soil temperature 68-75°F (20-24°C)
- Air temperature 68-70°F (20-21°C) nights, 70-75°F (21-24°C) days.

  To guarantee uniform rooting, the media should be
- sufficiently moist so that water is easily squeezed out of rooting media.
- Keep RH 75-90% at the base of the cutting.
- Use tempered water, 70°F (21°C), in the mist lines since cold water will lower the soil temperature during the day.
- Maintain high relative humidity in the air surrounding the cutting, 75-90%, to minimize evapotranspiration.
- Instead of heavy misting use white plastic over hoops with sides securely attached.
- Excessive moisture will delay rooting-- mist only 3-4 times per day.

- · Each wilting episode during stage 2 adds at least one day to the rooting program.
- Light intensity should be 500-1000 foot-candles.
- Light intensity above 1000 will increase plant stress due to plant warming.
- Use retractable shade so that the light intensity can be increased as the cuttings mature.
- Begin foliar feeding with 50-75 ppm of 20-10-20 as soon as there is any loss in foliage color.
- Soil pH should be 5.6-5.8 with an EC < 0.5.
- Maintain pH of media leachate at 5.6-5.8.
- If growth regulators were used during stock plant growth, no growth regulators are used during
- If growth regulators were not used during stock plant growth then start applying appropriate growth regulators as soon as cuttings are turgid.
- Once 50% of the cuttings begin differentiating root initials, the cuttings are ready to transfer to stage

#### **STAGE 3** - Root development (9-11 days)

- Soil temperature 68-75°F (20-24°C).
- Air temperature 68-70°F (20-21°C) nights, 70-75°F (21-24°C) days.
- Once the cuttings begin to form root initials, it is critical to begin drying out the soil.
- Avoid drying out the air since this will increase evapotranspiration which will reduce root zone temperature.
- To reduce soil moisture:
- Reduce the mist application during the dark
- Reduce the duration and frequency of the mist.
- Reduce the amount of water applied per day by delaying the start of the mist period until 9:30 to 11:00 AM and end the mist period earlier than 4:00-5:00 PM.
- Remove plastic at night once new roots are visible.
- Begin increasing light intensity to 1000-2000 ftc as the cuttings begin to root out.
- Apply growth regulators as needed.
  Foliar feed at 100 ppm nitrogen from 15-0-15 alternating with 20-10-20. Increase the frequency and rate at each application to prevent salt problems.
- The majority of fertilizer should be in the nitrate form (15-0-15).
- The soil pH should be 5.6-5.8.
- Soil EC should be below 0.5.
- Monitor the pH and EC of the leachate on a daily basis. The pH should be 6.0 and the EC should stay between .5-1.0.

**STAGE 4** - Plants ready for transplanting or shipping (7 days)

- Air temperatures 62-68°F (16-20°C) nights, 70-75° F (21-24°C) days.
- Move the liners form the mist area into an area of lower RH, lower temperatures, and higher light intensity.
- A zero ĎIF is desired.
- · Use growth regulators if DIF is positive.
- Increase the light intensity to 2000-4000 ftc.
- Provide shade during the mid point of the day to reduce temperature stress on the crop.
- Maintain soil pH 5.6-5.8 and EC less than 1.0 mmhos/cm.
- Fertilize at 150 ppm nitrogen from 15-0-15 alternating with 20-10-20 once per week.

# **Growing On to Finish**

## **TEMPERATURE**

Night: 62-65°F (16-18°C)

**Day:** 68-75°F (20-24°C)

#### **LIGHT**

- Keep light intensities at 4500-6000 while maintaining moderate temperatures.
- Marguerite daisies are day neutral but are affected by total amount of light. During the winter when sunlight is reduced, crops take longer to finish.
- Low light levels promote stem stretch.
- HID (ftc) for 18 hours per day can reduce crop time.

#### **MEDIA**

- Use a well-drained, disease-free soil-less medium with a high initial nutrient charge and a pH 6.0-6.5.
- Combinations of peat, bark, or perlite are best.

#### **WATER**

- Keep soil moist.
- Don't water in the late afternoon to avoid wet foliage in the evening. Botrytis can be a problem with Felicia daisies.

### **FERTILIZATION**

- Marguerite daisy has a light/moderate fertilizer requirement.
- 15-0-15 alternating with 20-10-20 is best.
- As the plants mature the rate can be increased to 150-200 ppm.
- Water with clear water every third watering if high soluble salts problems occur.
- Maintain medium electrical conductivity around 1.0

- mmhos/cm (using 1:2 extraction).
- Excessive potassium will cause magnesium deficiency symptoms (interveinal chlorosis)

# **PINCHING**

- Pinch plants 3-4 days after potting or once plants are rooted to the edge of the container.
- Pinch above the 5th or 6th set of leaves about 1-1.5" above the soil line.

#### **CONTROLLING HEIGHT**

Height can be controlled by withholding fertilizer, especially phosphorous and ammonium-form nitrogen.

# **PLANT GROWTH REGULATORS**

- Felicia responds well to a drench of 5000 ppm Cycocel 5-6 days after the first pinch.
- Felicia responds well to B-Nine. A drench of 5000 ppm B-Nine 5-6 days after pinching is highly effective. Re-apply every 2 weeks as needed.
- As the light intensity increases, reduce the rate to 2500 ppm

#### POST PRODUCTION CARE

#### **TEMPERATURE**

Night: 55-65°F (13-18°C)

**Day:** 68-75°F (20-24°C)

## LIGHT

- Marguerite daisy does best in full sun under cooler temperatures.
- Optimum light levels are 4500-6000 ftc.

#### **MOISTURE**

- Felicia Daisy is susceptible to stem collapse and Botrytis if kept too wet.
- Keep soil moist, but avoid wet foliage.

# **COMMON PROBLEMS:**

Insects: Aphids, Thrips, Worm, Spider mites, Fungus gnats

Diseases: Botrytis, Rhizoctonia, Pythium,

Phytophthora, Stem Canker

#### COMMON PROBLEMS AND CAUSES:

Problem: Plants collapse

Causes: Wet media for an extended period; Botrytis

Problem: Excessive vegetative growth

Causes: High nitrogen concentration in the soil; Over

fertilization under low light; Low light and over

watering, wet media

Problem: Poor branching Causes: Low fertilization during early stages

Problem: Foliage Necrosis Causes: Drying out the plant between irrigations
